FOREWORD

The Pond Dynamics/Aquaculture Collaborative Research Support Program (PD/A CRSP) represents an international community of researchers and institutions dedicated to strengthening health and nutrition in developing countries by improving the efficiency of pond aquaculture systems. It is one of several agricultural CRSPs supported by the U.S. Agency for International Development under the authority of Title XII of the International Development and Food Assistance Act of 1975.

The "Global Experiment" in Pond Dynamics/Aquaculture is the major CRSP research activity, covering the period from 1982 to 1987. The Global Experiment was designed to quantitatively describe the physical, chemical and biological principles of pond culture systems. The information gained from the Global Experiment will be used to improve production technologies and develop quantitative production functions to facilitate rigorous economic analyses of aquaculture systems.

Standardization is a key element of the Global Experiment. Standardization permits the comparison of data from diverse geographic locations. The experimental design involves monitoring specified environmental and fish production variables in accordance with standardized work plans in twelve or more ponds at each of seven geographical locations. The variables observed, frequency of observation, and materials and methods are uniform for all locations. The field data are filed in a centralized data base, called the CRSP Central Data Base. Statistical methods will be used to test hypotheses about correlations between variables and to evaluate the sources of variance within ponds, between ponds within locations, and between locations.

The CRSP Central Data Base will be used to develop predictive models of the processes occurring in pond culture systems. The models will be used to: provide guidance for ongoing and future research; predict the performance of existing and proposed pond systems subject to specific inputs and constraints; and improve the operation and efficiency of pond culture systems.

The Global Experiment includes three cycles of experiments. Each cycle consists of two series of observations, one during the dry season and one during the wet season. The objective of the first cycle is to create a detailed baseline of chemical, physical, and biological data on all ponds treated with a standard level of inorganic fertilizer. In the second experimental cycle, ponds treated with inorganic fertilizer are compared to ponds treated with organic fertilizer. In the third cycle, the responses of ponds to different levels of organic fertilizer are compared.

The goal of the Pond Dynamics/Aquaculture Collaborative Research Data Reports (referred to as Data Reports) is to record the CRSP Central Data Base and to present interpretations of site specific results. The Pond Dynamics/Aquaculture CRSP has conducted the Global Experiment at seven project sites in six developing countries: Thailand, Indonesia, the Philippines, Panama, Honduras, and Rwanda. The first volume of these reports provides descriptive information for each CRSP site. It presents the physical characteristics of each site, including a geographical sketch, climatology, and water and soil analyses. Experimental cycles are described in CRSP Work Plans One to Three, which are summarized in the first volume.

Volume One will serve as the reference volume for the entire report series. Subsequent volumes will focus on each site separately. Each Data Report will include one cycle (wet and dry seasons) of the Pond Dynamics/Aquaculture CRSP Global Experiment. Therefore, with few exceptions, each project site will have three Data Reports devoted to it, representing the results of the three cycles of the Global Experiment. Cycle III of the Global Experiment in Honduras is presented in this volume.

INTRODUCTION

The Pond Dynamics/Aquaculture CRSP has been studying the dynamics of tilapia production ponds in the tropics subjected to differing nutrient additions since the initiation of field experiments in January 1984. A low level of phosphorus, as triple-superphosphate, was added to ponds during the rainy and dry seasons of the first year's experiments; fish yield was less than half that expected due to, in the case of Honduras, severe clay turbidity in all ponds (Green et al., 1986). During the Cycle II dry season, organic and inorganic forms of nutrients were tested (Green et al., 1987). Similar amounts of nitrogen and phosphorus as layer chicken litter, dairy cow manure, or chemical fertilizer (urea and triple-superphosphate) were added to ponds. Fish yields were greater when organic fertilizer was used. However, in the chemical fertilizer treatment fish yield was greater than that obtained during the first year's experiments, probably resulting from the greater quantities of phosphorus added, the inclusion of nitrogen, or a combination of both factors (Green et al., 1987). Fish yield during the Cycle II rainy season was also greater when chicken litter was the nutrient source (Green et al., 1988). Hence, organic fertilization consistently resulted in greater fish yield than did chemical fertilization, as both autotrophic and heterotrophic production were stimulated by the former; also, fish may have consumed some manure directly.

In an attempt to generate information of more immediate practical applicability to the host countries, and because chicken litter had proven to be a productive nutrient source, the CRSP initiated the present study to determine the yield of tilapia in ponds fertilized with differing rates of chicken litter. Weekly applications of layer chicken litter were made at rates of, on a total solids (TS) basis: 125 kg, 250 kg, 500 kg, and 1000 kg/ha. Additionally, the effect of season on tilapia yield was studied.

MATERIALS AND METHODS

Twelve 0.1-ha earthen ponds located on the "El Carao" Aquacultural Experiment Station, in Comayagua, Honduras, were used during this study. Chicken litter, obtained from a local commercial layer operation, was purchased in bulk for each experiment and stored in woven plastic sacks under cover until broadcast over the pond surface at specified treatment rates. Three ponds were randomly assigned to each treatment during each season. Manure total solids was determined prior to each application, with the wet weight of manure applied being corrected accordingly. The nitrogen, phosphorus, potassium, and organic matter content of the manure was determined (Jackson, 1958).

Ponds were stocked with populations of male *Oreochromis niloticus* (Egna et al., 1987). Mean fingerling weight (g/fish) was 26.1 and 36.6 during the rainy and dry season, respectively. Ponds were stocked on 5 June 1986 for the rainy season experiment; all ponds were harvested on 5 November 1986, 152 days after stocking. Ponds for

the dry season experiment were stocked on 7 February 1987 and harvested on 8 July 1987, 150 days later. Ponds were managed according to guidelines given in Egna et al. (1987).

Selected water chemistry variables were determined on a weekly basis, meteorological variables were measured 5 days per week, and water and mud samples were analyzed at the beginning and end of each experiment (Egna et al., 1987). The free-water diurnal curve method (Hall and Moll, 1975) was used to measure primary productivity every 2 weeks; measurements were made at 4-hour time and at 0.25-m depth intervals. Values were corrected for oxygen diffusion across the air-water interface using an empirical relationship which relates the oxygen transfer coefficient to wind speed (Banks and Herrera, 1977).

Data were analyzed using analysis of variance and regression analysis; when necessary, log transformation of data was carried out (Feldman and Gagnon, 1986). Data were reported as means by pond, and means \pm standard error by treatment; differences between treatments were determined using the t-test. Differences were declared significant at alpha level 0.05.

RESULTS

FISH YIELD

Tilapia yield increased as the rate of chicken litter application increased, and ranged from 934 to 2451 kg/ha in 152 days, and from 1085 to 2363 kg/ha in 150 days during the rainy and dry seasons (Table 1, Figure 1). Mean individual weights of stocked fish at harvest ranged from 91.1 to 221.4 g and from 106.6 to 279.5 g during the rainy and dry seasons. Reproduction occurred in ponds during both seasons, although independently of fertilization rate; reproduction represented from 4.0 to 15.3% and 0 to 7.9% of the fish yield during the rainy and dry seasons. Reduced amounts of reproduction were observed when a larger sized fingerling was sexed (as during the dry season).

No seasonal differences in yield, net total yield, or daily yield were observed (Table 2). Greater reproduction was observed in the 250 and 500 kg/ha fertilization rates during the rainy season, indicating that the larger the fingerling at sexing, the more effective the separation of sexes. In the 1000 kg/ha per week treatment, fish survival was greater during the wet season; however, yield was not affected as the individual weight of fish harvested during the dry season was greater. Pooled tilapia yield (y) data and manure application rate (x) were subjected to regression analysis resulting in a quadratic relationship ($y = 864.6 + 2.80x - 0.001x^2$, $r^2 = 0.897$) (Figure 2).

WATER QUALITY VARIABLES

Mean water quality variables are summarized by pond in Tables 3 and 4, and by treatment in Figures 3 to 10. Water quality variable treatment means and comparisons (t-test) are shown in Table 5.

BIOLOGICAL VARIABLES

Secchi Disk Visibility

Mean Secchi disk visibility ranged from 9.2 to 21.5 cm during the rainy season and from 12.7 to 25.0 cm during the dry season. Differences were observed among treatment means during the rainy season: means in the 250 and 500 kg treatments were similar. The 125 kg treatment mean was significantly less than all other means, and the 1000 kg treatment mean was significantly greater than all other means. During the dry season, mean Secchi disk visibility was similar in the 125, 250, and 500 kg treatments, and less than the mean for the 1000 kg treatment. The only seasonal difference observed was for the 1000 kg treatment where mean visibility was greater during the dry season. As in previous experimental cycles, clay turbidity interfered with Secchi disk readings.

Chlorophyll a

Mean chlorophyll a concentrations varied from 27.98 to 167.89 and from 43.50 to 209.76 mg/m³ during the rainy and dry seasons. Significant increases in mean chlorophyll a concentrations were obtained with increases in the amount of chicken litter applied (Figure 11). Mean chlorophyll a concentrations were similar during both seasons in all treatments except for the 125 kg/ha per week treatment where the dry season mean was greater.

Primary Productivity and Community Respiration

Primary productivity and community respiration are summarized as means by pond (Table 6), and as seasonal comparisons by treatment (Table 7). Mean net primary productivity ranged from 1.15 to 6.45 and from 1.49 to 7.90 g O₂/m³ per day during the rainy and dry seasons. The same ranges for gross primary productivity were 3.61 to 14.17 and 4.59 to 15.52 g O₂/m³ per day. Community respiration means varied from 4.46 to 15.44 and from 6.20 to 15.23 g O₂/m³ per day during the rainy and dry seasons. Net and gross primary productivity and community respiration all increased significantly with increasing rates of fertilization (Figures 12-14). Net primary productivity was greater during the dry season for the 500 and 1000 kg/ha per week treatments. Community respiration and gross primary productivity were similar during both the rainy and dry seasons for all treatments.

Manure

The layer chicken litter (consisting of pine sawdust, manure, feathers and waste feed) used in both studies was obtained from the same source and had the following mean \pm SD nutrient concentrations, expressed as % of total solids, during the rainy and dry seasons, respectively: total nitrogen: 2.24 ± 0.10 and 2.17 ± 0.15 ; phosphorus: 1.12 ± 0.10 and 1.25 ± 0.05 ; and, total solids: 88.25 ± 1.86 and 89.47 ± 2.06 .

Soils

Results from initial and final soil analyses for each season are shown in Tables 8 and 9. During the rainy season: no changes in total N were observed within treatments; P declined, but was significant only in the 125 kg/ha per week treatment; cation exchange capacity (CEC) was similar except in the 125 kg treatment where it increased; and soil pH generally decreased, although only in the 125 kg/ha per week treatment was it significant. During the dry season: soil organic matter increased significantly in the 500 and 1000 kg/ha per week treatments; total N increased in all treatments as did P; CEC was unchanged; and pH, although lower in all treatments, was significant only in the 1000 kg/ha per week treatment.

Minor Elements in Water

Results of minor element analyses of pond water are presented in Table 10 and 11. Final concentrations within treatments were generally greater during both seasons for Cl, Ca, Fe, Mg, K, Cu, and Zn.

Meteorological Variables

Weather data are shown by month in Table 12.

RELATIONSHIPS AMONG VARIABLES

Regression analyses were performed among selected variables. Tilapia yield was correlated with net and gross primary productivity, community respiration, and chlorophyll *a* concentration (Figures 15-18). Net and gross primary productivity, and community respiration each correlated with chlorophyll *a* (Figures 19-21). Neither tilapia production nor chlorophyll *a* concentration correlated with Secchi disk visibility, due to the inhibitory effect of the clay turbidity in ponds on Secchi disk visibility.

DISCUSSION

Chicken litter, independent of application rate, was effective in stimulating tilapia growth. However, season did not significantly affect fish yield, water quality variables or indicators of primary productivity. Fish yields obtained during these two experiments were the greatest yet obtained during the Honduras Pond Dynamics/Aquaculture CRSP. Cycle II results demonstrated that chicken litter, applied at 500 kg/ha per week, was a more effective fertilizer for increasing fish yield than fresh cow manure or high doses of chemical fertilizer (Green et al., 1987). Tilapia yield was further increased through greater applications of chicken litter as demonstrated by the results of the Cycle III studies. Layer chicken litter applied at 1000 kg/ha per week resulted in the greatest tilapia yield. Significant increases in tilapia yield would not result from manure applications greater than 1000 kg/ha per week as chronic low dissolved oxygen and deteriorated water quality would result in increased tilapia mortality (McGeachin and Stickney, 1982; Hopkins et al., 1983). At the highest rate of manure application in the Cycle III studies, 143 kg/ha per day of dry matter were applied to the ponds. Rates of up to 210 kg/ha per day dry matter have been added to ponds with no adverse consequences, but for short duration (Moav et al., 1977). Hefher and Pruginin (1981) recommended a maximum application of 120 kg/ha per day dry matter as manure.
